We study heavy-heavy and heavy-light quark systems for charm with a relativistic heavy quark action in $2+1$ flavor lattice QCD. Configurations are generated by the PACS-CS Collaboration at the lattice spacing is $a = 0.09$ fm with the lattice size of $32^3 \times 64$ employing the $O(a)$-improved Wilson quark action and the Iwasaki gauge action. We present preliminary results for the charmonium spectrum and the D and D_s meson decay constants evaluated at 3.5 MeV$< m_{\rm ud} <$ 12 MeV with $m_{\rm s}$ around the physical value. We investigate the dynamical quark mass dependences of the hyperfine and the orbital splittings. The decay constants are compared with the recent experimental values.

1. Introduction

Precise determination of physical quantities for heavy quark systems provides us with an opportunity to search for new physics beyond the standard model. For this purpose lattice QCD should be a powerful tool. However, the use of conventional lattice quark actions are problematic because of large cutoff errors due to the heavy quark masses. So far several approaches to avoid this problem have been employed for the study of heavy quark physics on the lattice[1]. Our choice is to employ the relativistic heavy quark action of Ref. [2]. This formalism allows us to take the continuum limit in which $m_Q a$ corrections are controlled by a smooth function. In fact the cutoff errors are reduced from $O((m_Q a)^n)$ to $O(f(m_Q a)(a\Lambda_{QCD})^2)$ where $f(m_Q a)$ is an analytic function around $m_Q a = 0$.

2. Simulation parameters

We simulate the charm quark system with the relativistic heavy quark action of Ref. [2] on the 2+1 flavor lattice QCD configurations which are generated by the PACS-CS Collaboration employing the nonperturbatively $O(a)$-improved Wilson quark action with $c_{\rm SW}^{\rm NP} = 1.715$[3] and the Iwasaki gauge action. The lattice size is $32^3 \times 64$ whose spatial extent is $L = 2.9$ fm with the lattice spacing of $a = 0.09$ fm. The dynamical up-down quark mass ranges from 67 MeV down to 3.5 MeV which is close to the the physical value. The details of the configuration production and light hadron physics that emerges from them are described in Refs. [4, 5, 6, 7]. Table 1 summarizes the simulation parameters and the statistics of the configuration sets we have used for the heavy quark measurements. The number of the source points is to be quadrupled. We emphasize that the data point at $(\kappa_{\rm ud}, \kappa_{\rm s})$=(0.137785,0.13660) is almost on the physical point: the up-down quark mass is only 30% heavier and the strange quark mass is almost exactly at the physical value.

The relativistic heavy quark action proposed in Ref. [2] is given by

$$S_Q = \sum_{x,y} \overline{Q}_x D_{x,y} Q_y, \tag{2.1}$$

$$\begin{aligned} D_{x,y} = {} & \delta_{xy} - \kappa_{\rm h} \sum_i \left[(r_s - \nu\gamma_i) U_{x,i} \delta_{x+\hat{i},y} + (r_s + \nu\gamma_i) U^\dagger_{x,i} \delta_{x,y+\hat{i}} \right] \\ & - \kappa_{\rm h} \left[(r_t - \nu\gamma_i) U_{x,4} \delta_{x+\hat{4},y} + (r_t + \nu\gamma_i) U^\dagger_{x,4} \delta_{x,y+\hat{4}} \right] \\ & - \kappa_{\rm h} \left[c_B \sum_{i,j} F_{ij}(x) \sigma_{ij} + c_E \sum_i F_{i4}(x) \sigma_{i4} \right], \end{aligned} \tag{2.2}$$

where we are allowed to choose $r_t = 1$, while the other four parameters ν, r_s, c_B, c_E should be adjusted in the mass dependent way. We use the one-loop perturbative values for r_s, c_B and c_E evaluated in Ref. [8]. For the clover coefficients c_B and c_E we incorporate the nonperturbative contributions at the massless limit adopting the procedure $c_{B,E} = (c_{B,E}(m_Q a) - c_{B,E}(0))^{\rm PT} + c_{\rm SW}^{\rm NP}$. At each simulation point, the parameter ν is nonperturbatively determined from the dispersion relation for the spin-averaged $1S$ state of the charmonium:

$$E(\vec{p})^2 = E(\vec{p})^2 + c_{\rm eff}^2 |\vec{p}|^2, \tag{2.3}$$

Table 1: Simulation parameters. Quark masses are perturbatively renormalized in the $\overline{\rm MS}$ scheme. The renormalization scale is $\mu = 1/a$ for $\kappa_{\rm ud} \leq 0.137785$ and $\mu = 2$ GeV for the physical point.

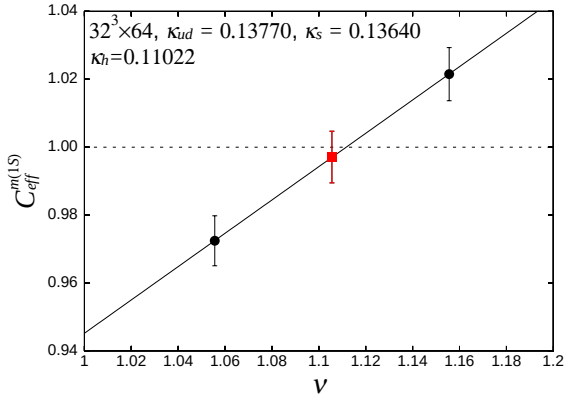

Figure 1: Nonperturbative tuning of ν with $\kappa_{\rm h} = 0.11022$ at $(\kappa_{\rm ud}, \kappa_{\rm s})$=(0.13770,0.13640). A red symbol denotes the result for the nonperturbative ν.

where ν is adjusted such that the effective speed of light $c_{\rm eff}$ becomes unity. Figure 1 shows an example of the nonperturbative tuning of ν with $\kappa_{\rm h} = 0.11022$ at $(\kappa_{\rm ud}, \kappa_{\rm s})$=(0.13770,0.13640). In order to search for the physical charm quark mass point, we employ two values of the hopping parameter of a heavy quark $\kappa_{\rm h}$. The values of $\kappa_{\rm h}$ are chosen to sandwich the physical charm quark mass.

3. Heavy-heavy system

Let us first investigate the charmonium spectrum. At each combination of $(\kappa_{\rm ud}, \kappa_{\rm s})$ we determine the physical point of the charm quark by the condition that the mass of the spin-averaged $1S$ state reproduces the experimental value, $M(1S) = (M_{\eta_c} + 3M_{J/\psi})/4 = 3.0677(3)$ [GeV][9]. For this purpose we linearly interpolate the results for $M(1S)$ at two values of the hopping parameter $\kappa_{\rm h}$. Figure 2 illustrates this procedure for the case of $(\kappa_{\rm ud}, \kappa_{\rm s})$=(0.13770,0.13640).

In Fig. 3 we plot results for the mass of the orbital excitation $m_{\chi_{c1}}(1P) - m_{J/\psi}(1S)$ at the physical point of the charm quark mass. It is hard to detect the dynamical quark mass dependence within the errors in the range of 3.5MeV$\lesssim m_{\rm ud} \lesssim$12MeV and 73MeV$\lesssim m_{\rm s} \lesssim$90MeV. A very short chiral extrapolation is made employing a linear function of the up-down and the strange quark

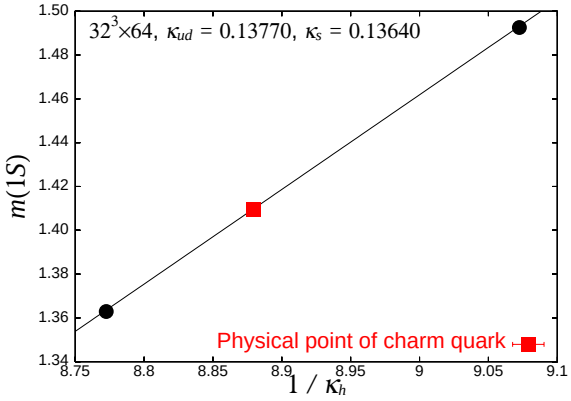

Figure 2: Interpolation of the spin-averaged $1S$ charmonium mass to the physical point as a function of $\kappa_{\rm h}$. Errors are within symbols.

masses:

$$m_{\chi_{c1}}(1P) - m_{J/\psi}(1S) = \alpha + \beta m_{\rm ud} + \gamma m_{\rm s}. \tag{3.1}$$

In Fig. 3 we find that the extrapolated value and its error are almost identical to the result at $(\kappa_{\rm ud}, \kappa_{\rm s})$=(0.137785,0.13640). This illustrates how close our simulation points are to the physical point. The result at the physical point is consistent with the experimental value within the error.

Figure 4 shows the results for the hyperfine splitting $m_{J/\psi} - m_{\eta_c}$. As in the orbital excitation we find little dynamical quark mass dependence. We extrapolate the results to the physical point employing a linear function of the dynamical quark masses. The extrapolated value, which is essentially determined by the result at $(\kappa_{\rm ud}, \kappa_{\rm s})$=(0.137785,0.13640), shows a 10% deficit from the experimental value. Possible sources of the discrepancy are $O(g^2a)$ effects in the relativistic heavy quark action, dynamical charm quark effects and disconnected loop contributions. A recent 2+1 flavor lattice QCD calculation with the highly improved staggered quarks[10] shows a similar value to ours.

We compare our results for the hyperfine splitting in $N_f = 2+1$ QCD with the previous $N_f = 0, 2$ results[11, 12] in Fig. 5. We observe a clear trend that the results become closer to the experimental value as the number of the flavor is increased. The dynamical quarks give significant contributions to the hyperfine splitting.

4. Heavy-light system

For the heavy-light system we focus on the D and D_s mesons and their decay constants measured at $(\kappa_{\rm ud}, \kappa_{\rm s})$=(0.137785,0.13660). This data point is so close to the physical point that $m_{\rm ud}$ corrections in the results could be smaller than the statistical errors. We employ perturbative values for the renormalization factor and the improvement coefficients of the axial vector current evaluated in Ref. [13]. For $c_{A_4}^+$ we incorporate the nonperturbative contribution at the massless limit by $c_{A_4}^+ = (c_{A_4}^+(m_Q a) - c_{A_4}^+(0))^{\rm PT} + c_A^{\rm NP}$ with $c_A^{\rm NP} = -0.03876106$[14]. Figure 6 compares our results for the D and D_s meson masses with the experimental values [15]. They are consistent within

the errors. It is noteworthy that the physical charm quark mass determined from the heavy-heavy system successfully reproduces the heavy-light meson masses. The results for the decay constants are shown in Fig. 7, where we also plot the recent 2+1 flavor lattice QCD results with relativistic heavy quark actions[16, 17] for comparison. Although we find a sizable discrepancy between our result and the experimental value for f_{D_s}, we should analyze the full configuration set and improve statistics before we derive any conclusions.

In Fig. 8 we plot the ratios of f_{D_s} to f_D and f_{D_s} to f_K in which uncertainties coming from the perturbative renormalization factors and the lattice cutoff should cancel out. For both cases our results show larger values than the experimental ones, which originate from the discrepancy found in Fig. 7.

Acknowledgments
